Summary

CAWSR facilitates the testing of the open-source autonomous driving system, Autoware, within CARLA ([Dosovitskiy et al., 2017](#)), the state-of-the-art open-source driving simulator. Building on existing tools, this project introduces a research-oriented testing framework for the execution of complex driving scenarios, as well as supporting implementation of a wide range of verification strategies.

Statement of Need

The aim of this project is to address the technical challenges associated with verification of complex autonomous driving systems (ADS) such as Autoware ([Kato et al., 2018](#)) or Baidu's Apollo ([Baidu Apollo team \(2017\)](#), [Apollo: Open Source Autonomous Driving, n.d.](#)). CARLA is the choice of the simulator for this tool due its rich ecosystem of open-source tooling and its prominence in the domain of autonomous vehicles. Alternatives such as BeamNG ([Maul et al., 2021](#)) or AWSIM ([Tier4/AWSIM, 2025](#)) have recently been rising in popularity, specifically designed for natively integrating AD systems such as Autoware. However CARLA still remains the standard choice in end-to-end testing of autonomous vehicles in the autonomous driving testing research community.

In practice, maintaining a consistent testing environment is essential, as simulators can introduce unintentional nondeterminism leading to inconsistent evaluation results ([Osikowicz et al., 2025](#)). While support for Autoware within the CARLA simulator exists, it does not currently extend to scenario-based testing, a critical component in established frameworks like the CARLA Leaderboard ([Team, 2024](#)) and its execution engine, Scenario Runner.

By adhering to the widely used CARLA platform rather than nascent alternatives, this paper introduces a framework directly built on established projects within the CARLA community, facilitating direct comparison with state-of-the-art driving agents evaluated on the CARLA Leaderboard, and ensuring that no additional non-determinism is introduced into the evaluation pipeline. The tool provides an extensible interface for algorithmic scenario generation and optimisation, supporting a wide range of verification strategies based on common evaluation metrics such as CARLA Leaderboard's driving score.

Despite the increasing use of Autoware, there is still exists a clear lack of tooling for the testing and verification of the system in complex road scenarios. CAWSR aims to address this, enabling researchers to test Autoware in programmatically defined road scenarios, evaluating its safety and capability as an ADS.

37 State of the Field

38 As previously established, CARLA offers a rich ecosystem of tools and documentation. Multiple
39 frameworks already exist for supporting popular open-source AD systems, such as *apollo-carla-*
40 *bridge* (Guardstrikelab, 2023) for Apollo and *autoware-carla-bridge* (Kaljavesi et al., 2024) for
41 Autoware. These tools solve a key issue; transforming sensor and control data from CARLA to
42 formats supported by the each system. However, native support for scenario execution engines is
43 non-existent, restraining their use for scenario-based testing and verification. These techniques
44 significantly reduce the effort required to validate autonomous driving systems, lowering the
45 technical barrier of entry compared to alternative approaches such as mileage-based testing,
46 which require high startup costs.

47 The current standard for scenario execution within CARLA is the CARLA Leaderboard and
48 its execution engine, Scenario Runner (SR) (CARLA, 2025). Common use cases of these
49 frameworks include testing end-to-end driving models, such as those based on VLM (Vision
50 Language Models) or Reinforcement Learning. No support is included for testing ROS based
51 AD systems, which focus on a modular approach to autonomous driving, rather than end-to-end.
52 PCLA (Tehrani et al., 2025), a framework for CARLA, addresses the topic of scenario-testing by
53 creating a clear deployment pipeline for autonomous agents / systems into CARLA, including
54 Autoware. However, their methodology focuses on the simplification of agent implementation
55 and abstraction of setup across various CARLA versions. While this allows for quick use and
56 evaluation without relying on external codebases (such as the CARLA Leaderboard), there is
57 a clear gap on deep intergration between the agent and simulator, limiting the execution of
58 complex route-based scenarios.

59 Tool Summary

60 CAWSR is a fully synchronous testing-framework directly integrating Scenario Runner. It is
61 built and deployed as a Docker container alongside Autoware and includes two main modes
62 of operation. *Algorithm* mode supports the execution of custom verification strategies and
63 algorithms implemented by the user. *Benchmark* mode includes functionality to execute
64 and evaluate a set of scenario definitions empirically. A fully synchronous pipeline has been
65 developed to ensure no new non-determinism is introduced, although some may exist directly
66 within the simulator itself (Osikowicz et al., 2025).

67 To facilitate development, we introduce a new domain model for the definition of route-based
68 scenarios within CARLA, alongside a JSON implementation. This model is based on the format
69 introduced by Scenario Runner, facilitating support between both frameworks.
